Parallel Programming COMP5112

Parallel Program Development

Roadmap

- The n-body problem.
- The traveling salesman problem.

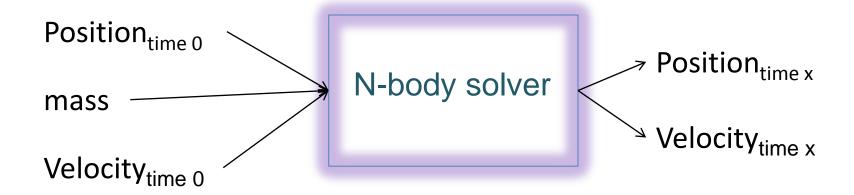

N-BODY SOLVERS

The n-body problem

 Find the positions and velocities of a collection of interacting particles over a period of time.

 An n-body solver is a program that finds the solution to an n-body problem by simulating the behavior of the particles.

Simulating motion of planets

- Determine the positions and velocities:
 - Newton's second law of motion.
 - Newton's law of universal gravitation.

Forces

$$\mathbf{f}_{qk}(t) = -\frac{Gm_q m_k}{\left|\mathbf{s}_q(t) - \mathbf{s}_k(t)\right|^3} \left[\mathbf{s}_q(t) - \mathbf{s}_k(t)\right]$$

$$\mathbf{F}_{q}(t) = \sum_{\substack{k=0\\k\neq q}}^{n-1} \mathbf{f}_{qk} = -Gm_{q} \sum_{\substack{k=0\\k\neq q}}^{n-1} \frac{m_{k}}{\left|\mathbf{s}_{q}(t) - \mathbf{s}_{k}(t)\right|^{3}} \left[\mathbf{s}_{q}(t) - \mathbf{s}_{k}(t)\right]$$

Acceleration

$$\mathbf{s}_q''(t) = -G \sum_{\substack{j=0\\j\neq q}}^{n-1} \frac{m_j}{\left|\mathbf{s}_q(t) - \mathbf{s}_j(t)\right|^3} \left[\mathbf{s}_q(t) - \mathbf{s}_j(t)\right]$$

$$t = 0, \Delta t, 2\Delta t, \dots, T\Delta t$$

Serial pseudo-code

```
Get input data;
for each timestep {
   if (timestep output) Print positions and velocities of particles;
   for each particle q
        Compute total force on q;
   for each particle q
        Compute position and velocity of q;
}
Print positions and velocities of particles;
```

Computation of the forces

```
for each particle q {
   for each particle k != q {
     x_diff = pos[q][X] - pos[k][X];
     y_diff = pos[q][Y] - pos[k][Y];
     dist = sqrt(x_diff*x_diff + y_diff*y_diff);
     dist_cubed = dist*dist*dist;
     forces[q][X] -= G*masses[q]*masses[k]/dist_cubed * x_diff;
     forces[q][Y] -= G*masses[q]*masses[k]/dist_cubed * y_diff;
}
```

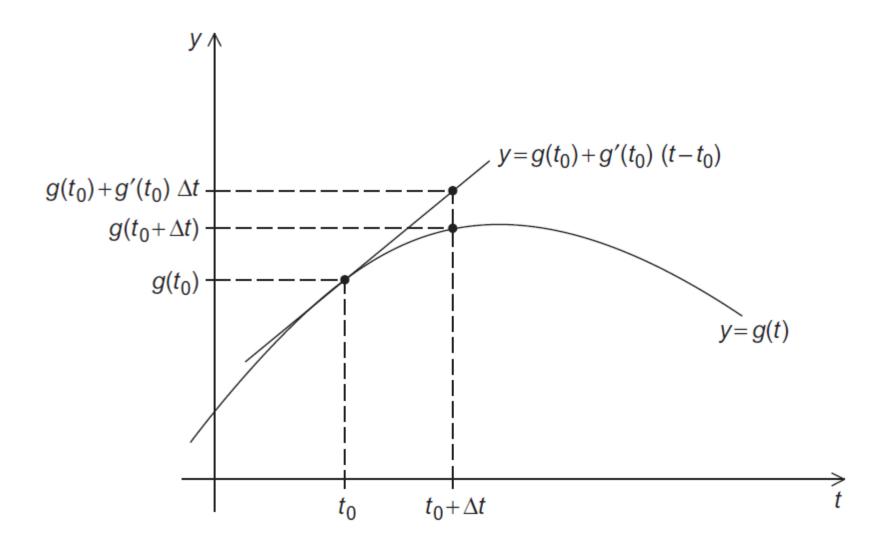

A Reduced Algorithm for Computing N-Body Forces

```
for each particle q
   forces[q] = 0;
for each particle q {
   for each particle k > q {
      x_diff = pos[q][X] - pos[k][X];
      y_diff = pos[q][Y] - pos[k][Y];
      dist = sqrt(x_diff*x_diff + y_diff*y_diff);
      dist cubed = dist*dist*dist:
      force_qk[X] = G*masses[q]*masses[k]/dist_cubed * x_diff;
      force_qk[Y] = G*masses[q]*masses[k]/dist_cubed * v_diff
      forces[q][X] += force_qk[X];
      forces[q][Y] += force_qk[Y];
      forces[k][X] -= force_qk[X];
      forces[k][Y] = force_qk[Y];
```

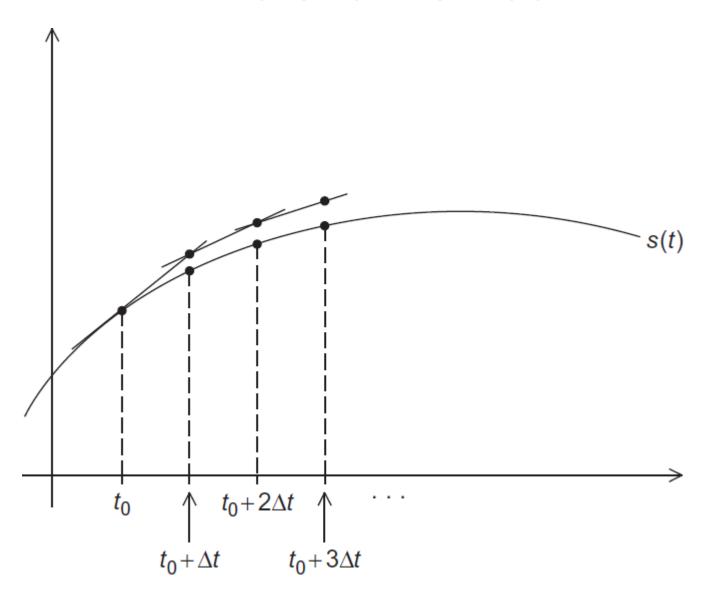

The individual forces

$$\begin{bmatrix} 0 & \mathbf{f}_{01} & \mathbf{f}_{02} & \cdots & \mathbf{f}_{0,n-1} \\ -\mathbf{f}_{01} & 0 & \mathbf{f}_{12} & \cdots & \mathbf{f}_{1,n-1} \\ -\mathbf{f}_{02} & -\mathbf{f}_{12} & 0 & \cdots & \mathbf{f}_{2,n-1} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ -\mathbf{f}_{0,n-1} & -\mathbf{f}_{1,n-1} & -\mathbf{f}_{2,n-1} & \cdots & 0 \end{bmatrix}$$

Using the Tangent Line to Approximate a Function

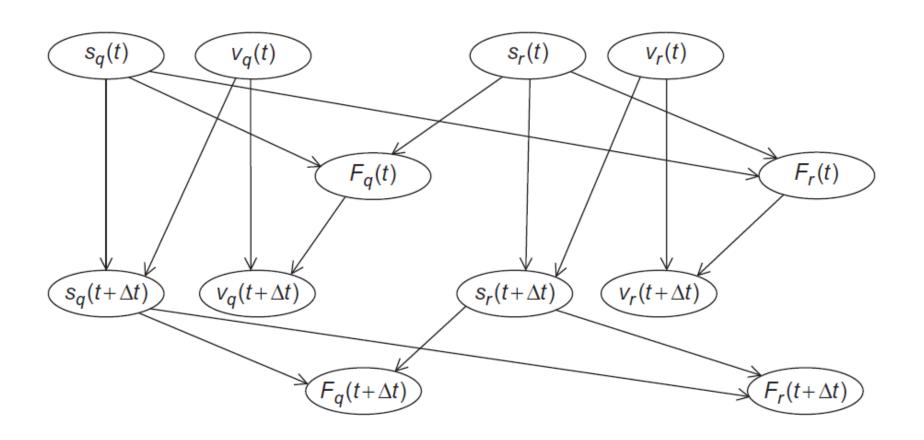

Euler's Method

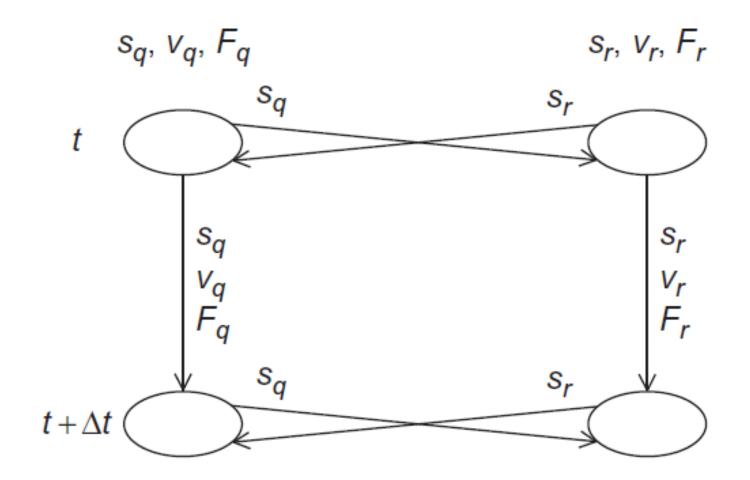

Parallelizing the N-Body Solvers

- Apply Foster's methodology.
- Initially, we want a lot of tasks.
- Start by making our tasks the computations of the positions, the velocities, and the total forces at each timestep.

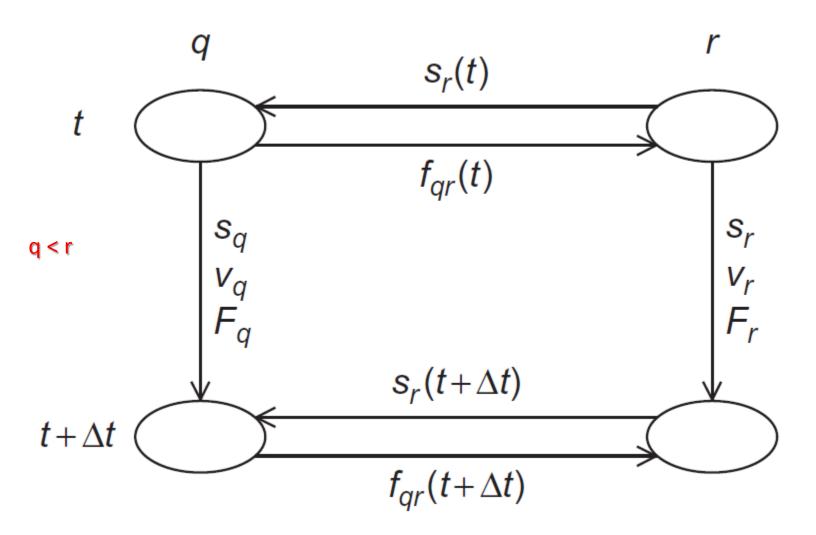

Communications Among Tasks in the Basic N-Body Solver

Communications Among Agglomerated Tasks in the Basic N-Body Solver

Communications Among Agglomerated Tasks in the Reduced N-Body Solver

Computing the total force on particle q in the reduced algorithm

```
for each particle k > q {
   x_diff = pos[q][X] - pos[k][X];
   y_diff = pos[q][Y] - pos[k][Y];
  dist = sqrt(x_diff*x_diff + y_diff*y_diff);
   dist_cubed = dist*dist*dist;
   force_qk[X] = G*masses[q]*masses[k]/dist_cubed * x_diff;
   force_qk[Y] = G*masses[q]*masses[k]/dist_cubed * y_diff;
   forces[q][X] += force_qk[X];
   forces[q][Y] += force_qk[Y];
   forces[k][X] -= force_qk[X];
   forces[k][Y] = force_qk[Y];
```

Serial pseudo-code

In principle, parallelizing the two inner for loops will map tasks/particles to cores.

First attempt

```
for each timestep {
    if (timestep output) Print positions and velocities of particles;

# pragma omp parallel for
    for each particle q
        Compute total force on q;

# pragma omp parallel for
    for each particle q
        Compute position and velocity of q;
}
```

Let's check for race conditions caused by loop-carried dependences.

First loop

```
# pragma omp parallel for
for each particle q {
   forces[q][X] = forces[q][Y] = 0;
   for each particle k != q {
      x_diff = pos[q][X] - pos[k][X];
      y_diff = pos[q][Y] - pos[k][Y];
      dist = sqrt(x_diff*x_diff + y_diff*y_diff);
      dist_cubed = dist*dist*dist;
      forces[q][X] -= G*masses[q]*masses[k]/dist_cubed * x_diff;
      forces[q][Y] -= G*masses[q]*masses[k]/dist_cubed * y_diff;
   }
}
```

Second loop

```
# pragma omp parallel for
for each particle q {
   pos[q][X] += delta_t*vel[q][X];
   pos[q][Y] += delta_t*vel[q][Y];
   vel[q][X] += delta_t/masses[q]*forces[q][X];
   vel[q][Y] += delta_t/masses[q]*forces[q][Y];
}
```

Repeated forking and joining of threads

The same team of threads will be used

in both loops and for every iteration

of the outer loop.

pragma omp parallel
for each timestep {

if (timestep output) Print positions and velocities of particles;

pragma omp for
for each particle q

Compute total force on q;

pragma omp for
for each particle q

Compute position and velocity of q;

}

But every thread will print all the positions and velocities.

Adding the *single* directive

```
# pragma omp parallel
    for each timestep {
        if (timestep output) {
            pragma omp single
                Print positions and velocities of particles;
        }

# pragma omp for
        for each particle q
            Compute total force on q;

# pragma omp for
        for each particle q
            Compute position and velocity of q;
}
```

Parallelizing the Reduced Solver Using OpenMP

```
#
   pragma omp parallel
   for each timestep {
      if (timestep output) {
#
         pragma omp single
         Print positions and velocities of particles;
#
      pragma omp for
      for each particle q
         forces[q] = 0.0;
#
      pragma omp for
      for each particle q
         Compute total force on q;
#
      pragma omp for
      for each particle q
         Compute position and velocity of q;
```

Problems

$$\mathbf{F}_3 = -\mathbf{f}_{03} - \mathbf{f}_{13} - \mathbf{f}_{23}$$

Updates to forces[3] create a race condition.

In fact, this is the case in general.

Updates to the elements of the forces array introduce race conditions into the code.

First solution attempt

```
before all the updates to forces
pragma omp critical
   forces[q][X] += force_qk[X];
    forces[q][Y] += force_qk[Y];
    forces[k][X] = force_qk[X];
   forces[k][Y] = force_qk[Y];
           Access to the forces array will be effectively serialized!!!
```

Second solution attempt

```
omp_set_lock(locks[q]);
forces[q][X] += force_qk[X];
forces[q][Y] += force_qk[Y];
omp_unset_lock(locks[q]);

omp_set_lock(locks[k]);
forces[k][X] -= force_qk[X];
forces[k][Y] -= force_qk[Y];
omp_unset_lock(locks[k]);
```

Use one lock for each particle.

First Phase Computations for Reduced Algorithm with Block Partition

		Thread			
Thread	Particle	0	1	2	
0	0	$\mathbf{f}_{01} + \mathbf{f}_{02} + \mathbf{f}_{03} + \mathbf{f}_{04} + \mathbf{f}_{05}$	0	0	
	1	$-\mathbf{f}_{01} + \mathbf{f}_{12} + \mathbf{f}_{13} + \mathbf{f}_{14} + \mathbf{f}_{15}$	0	0	
1	2	$-\mathbf{f}_{02}-\mathbf{f}_{12}$	$\mathbf{f}_{23} + \mathbf{f}_{24} + \mathbf{f}_{25}$	0	
	3	$-\mathbf{f}_{03} - \mathbf{f}_{13}$	$-\mathbf{f}_{23} + \mathbf{f}_{34} + \mathbf{f}_{35}$	0	
2	4	$-\mathbf{f}_{04} - \mathbf{f}_{14}$	$-\mathbf{f}_{24} - \mathbf{f}_{34}$	f ₄₅	
	5	$-\mathbf{f}_{05} - \mathbf{f}_{15}$	$-\mathbf{f}_{25} - \mathbf{f}_{35}$	$-{\bf f}_{45}$	

First Phase Computations for Reduced Algorithm with Cyclic Partition

		Thread			
Thread	Particle	0	1	2	
0	0	$\mathbf{f}_{01} + \mathbf{f}_{02} + \mathbf{f}_{03} + \mathbf{f}_{04} + \mathbf{f}_{05}$	0	0	
1	1	$-{f f}_{01}$	$\mathbf{f}_{12} + \mathbf{f}_{13} + \mathbf{f}_{14} + \mathbf{f}_{15}$	0	
2	2	$-{f f}_{02}$	$-{f f}_{12}$	$\mathbf{f}_{23} + \mathbf{f}_{24} + \mathbf{f}_{25}$	
0	3	$-\mathbf{f}_{03} + \mathbf{f}_{34} + \mathbf{f}_{35}$	$-{f f}_{13}$	$-{f f}_{23}$	
1	4	$-\mathbf{f}_{04} - \mathbf{f}_{34}$	$-{\bf f}_{14}+{\bf f}_{45}$	$-{\bf f}_{24}$	
2	5	$-\mathbf{f}_{05} - \mathbf{f}_{35}$	$-{\bf f}_{15}-{\bf f}_{45}$	$-{f f}_{25}$	

Revised algorithm – phase I

```
pragma omp for
for each particle q {
   force_qk[X] = force_qk[Y] = 0;
   for each particle k > q {
      x_diff = pos[q][X] - pos[k][X];
      y_diff = pos[q][Y] - pos[k][Y];
      dist = sqrt(x_diff*x_diff + y_diff*y_diff);
      dist_cubed = dist*dist*dist;
      force_qk[X] = G*masses[q]*masses[k]/dist_cubed * x_diff;
      force_qk[Y] = G*masses[q]*masses[k]/dist_cubed * y_diff;
      loc_forces[my_rank][q][X] += force_qk[X];
      loc_forces[my_rank][q][Y] += force_qk[Y];
      loc_forces[my_rank][k][X] -= force_qk[X];
      loc_forces[my_rank][k][Y] -= force_qk[Y];
```

Revised algorithm – phase II

```
# pragma omp for
for (q = 0; q < n; q++) {
    forces[q][X] = forces[q][Y] = 0;
    for (thread = 0; thread < thread_count; thread++) {
        forces[q][X] += loc_forces[thread][q][X];
        forces[q][Y] += loc_forces[thread][q][Y];
    }
}</pre>
```

Parallelizing the Solvers Using Pthreads

- By default local variables in Pthreads are private. So all shared variables are global in the Pthreads version.
- The principle data structures in the Pthreads version are identical to those in the OpenMP version: vectors are two-dimensional arrays of doubles, and the mass, position, and velocity of a single particle are stored in a struct.
- The forces are stored in an array of vectors.

Parallelizing the Solvers Using Pthreads

- Startup for Pthreads is basically the same as the startup for OpenMP: the main thread gets the command line arguments, and allocates and initializes the principle data structures.
- The main difference between the Pthreads and the OpenMP implementations is in the details of parallelizing the inner loops.
- Since Pthreads has nothing analogous to a parallel for directive, we must explicitly determine which values of the loop variables correspond to each thread's calculations.

Parallelizing the Solvers Using Pthreads

- Another difference between the Pthreads and the OpenMP versions has to do with barriers.
- At the end of a parallel for OpenMP has an implied barrier.
- We need to add explicit barriers after the inner loops when a race condition can arise.
- The Pthreads standard includes a barrier.
- However, some systems don't implement it.
- If a barrier isn't defined we must define a function that uses a Pthreads condition variable to implement a barrier.

Parallelizing the Basic Solver Using MPI

- Choices with respect to the data structures:
 - Each process stores the entire global array of particle masses.
 - Each process only uses a single n-element array for the positions.
 - Each process uses a pointer loc_pos that refers to the start of its block of pos.
 - So on process 0 local_pos = pos; on process 1 local_pos = pos + loc_n; and so on.

Pseudo-code for the MPI version of the basic n-body solver

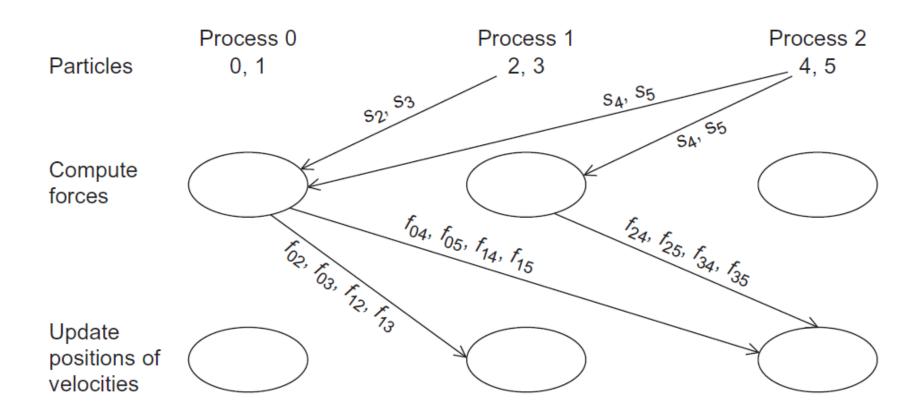

```
Get input data;
for each timestep {
   if (timestep output)
      Print positions and velocities of particles;
   for each local particle loc_q
      Compute total force on loc_q;
   for each local particle loc_q
      Compute position and velocity of loc_q;
   Allgather local positions into global pos array;
}
Print positions and velocities of particles;
```

Pseudo-code for output

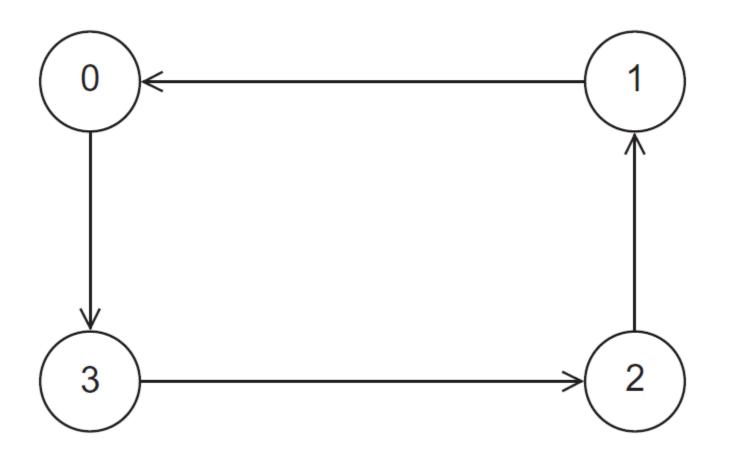

```
Gather velocities onto process 0;
if (my_rank == 0) {
   Print timestep;
   for each particle
     Print pos[particle] and vel[particle]
}
```

Communication In A Possible MPI Implementation of the N-Body Solver

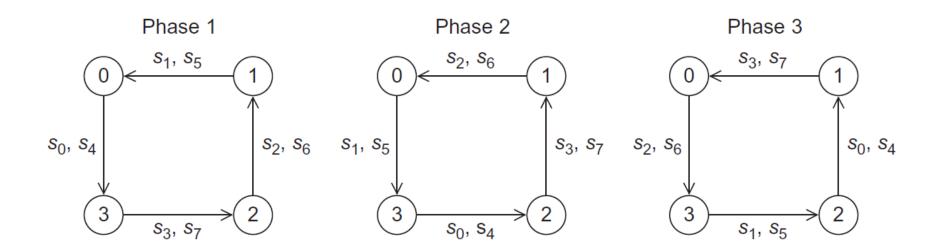

(for a reduced solver)

TREE SEARCH

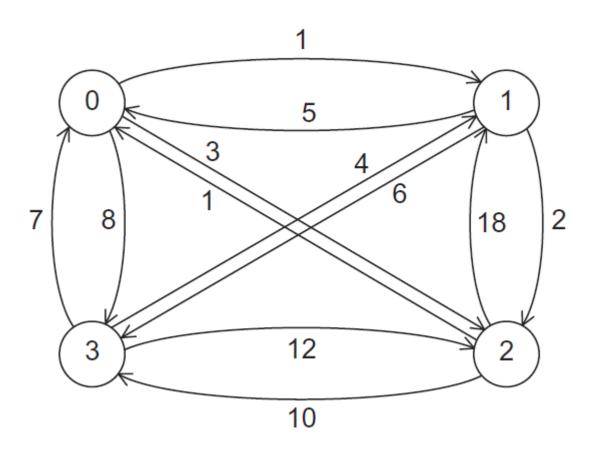

Traveling Salesperson problem (TSP)

 Find a minimum cost tour of all cities starting from home and returning home.

 An NP-complete problem. No known algorithm to TSP is faster in all cases than exhaustive search.

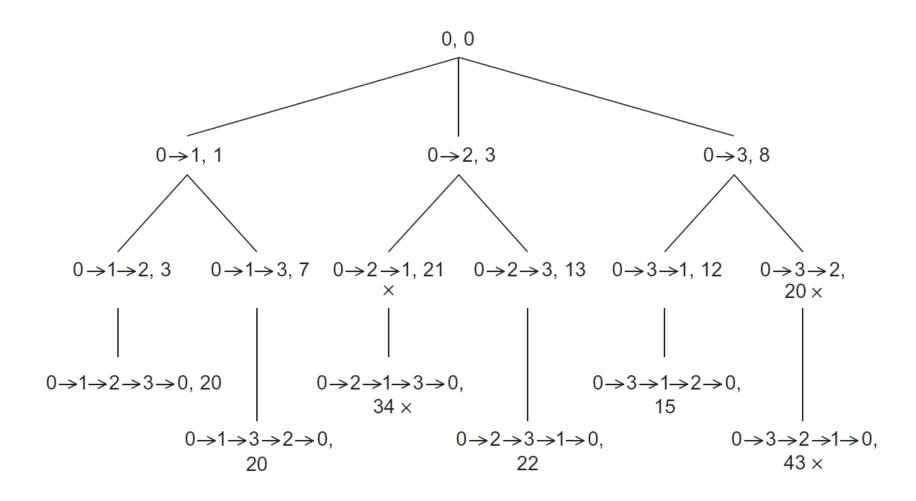

An example of using tree search to solve problems

A Four-City TSP

Search Tree for Four-City TSP

Pseudo-code for a recursive solution to TSP using depth-first search

```
void Depth_first_search(tour_t tour) {
   city_t city;
   if (City_count(tour) == n) {
      if (Best_tour(tour))
         Update_best_tour(tour);
   } else {
      for each neighboring city
         if (Feasible(tour, city)) {
            Add_city(tour, city);
            Depth_first_search(tour);
            Remove_last_city(tour);
  /* Depth_first_search */
```

Pseudo-code for an implementation of a depth-first solution to TSP without recursion

```
for (city = n-1; city >= 1; city--)
   Push(stack, city);
while (!Empty(stack)) {
   city = Pop(stack);
   if (city == NO_CITY) // End of child list, back up
      Remove last city(curr tour);
   else {
      Add_city(curr_tour, city);
      if (City_count(curr_tour) == n) {
         if (Best_tour(curr_tour))
            Update_best_tour(curr_tour);
         Remove_last_city(curr_tour);
      } else {
         Push(stack, NO_CITY);
         for (nbr = n-1; nbr >= 1; nbr--)
            if (Feasible(curr_tour, nbr))
               Push(stack, nbr);
```

Pseudo-code for a second solution to TSP that doesn't use recursion

```
Push_copy(stack, tour); // Tour that visits only the hometown
while (!Empty(stack)) {
   curr_tour = Pop(stack);
   if (City_count(curr_tour) == n) {
      if (Best_tour(curr_tour))
         Update_best_tour(curr_tour);
   } else {
      for (nbr = n-1; nbr >= 1; nbr--)
         if (Feasible(curr_tour, nbr)) {
            Add_city(curr_tour, nbr);
            Push_copy(stack, curr_tour);
            Remove_last_city(curr_tour);
   Free_tour(curr_tour);
```

Using pre-processor macros

```
/* Find the ith city on the partial tour */
int Tour_city(tour_t tour, int i) {
   return tour->cities[i];
} /* Tour_city */

/* Find the ith city on the partial tour */
   #define Tour_city(tour, i) (tour->cities[i])
```

Run-Times of the Three Serial Implementations of Tree Search

Recursive	First Iterative	Second Iterative			
30.5	29.2	32.9			

(in seconds)

The digraph contains 15 cities. All three versions visited approximately 95,000,000 tree nodes.

Making sure we have the "best tour" (1)

- When a process finishes a tour, it needs to check if it has a better solution than recorded so far.
- The global Best_tour function only reads the global best cost, so we don't need to tie it up by locking it. There's no contention with other readers.
- If the process does not have a better solution, then it does not attempt an update.

Making sure we have the "best tour" (2)

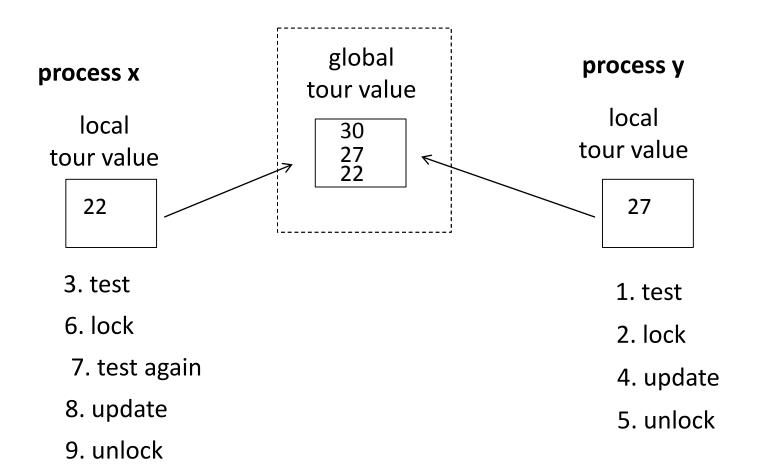

• If another thread is updating while we read, we may see the old value or the new value.

• The new value is preferable, but to ensure this would be more costly than it is worth.

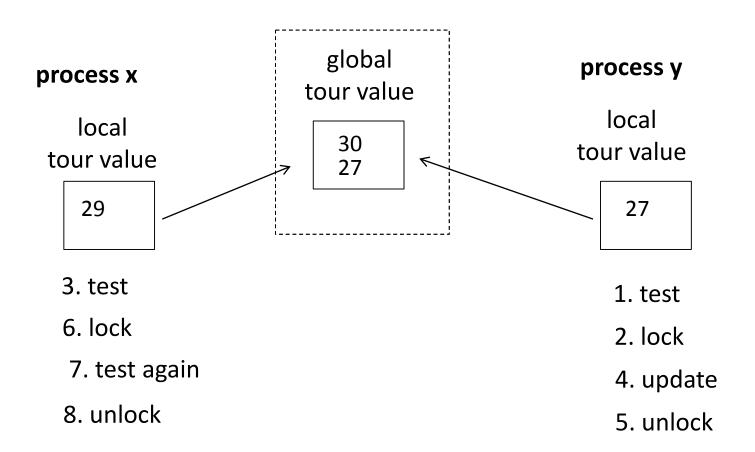

Making sure we have the "best tour" (3)

- In the case where a thread tests and decides it has a better global solution, we need to ensure two things:
 - 1) That the process locks the value with a mutex, preventing a race condition.
 - 2) In the possible event that the first check was against an old value while another process was updating, we do not put a worse value than the new one that was being written.
- We handle this by locking, then testing again.

First scenario

Second scenario

Pseudo-code for a Pthreads implementation of a statically parallelized solution to TSP

```
Partition tree(my rank, my stack);
while (!Empty(my_stack)) {
   curr tour = Pop(my stack);
   if (City_count(curr_tour) == n) {
      if (Best_tour(curr_tour)) Update_best_tour(curr_tour);
   } else {
      for (city = n-1; city >= 1; city--)
         if (Feasible(curr_tour, city)) {
            Add city(curr tour, city);
            Push_copy(my_stack, curr_tour);
            Remove_last_city(curr_tour)
  Free_tour(curr_tour);
```

Dynamic Parallelization of Tree Search Using Pthreads

- Termination issues.
- Code executed by a thread before it splits:
 - It checks that it has at least two tours in its stack.
 - It checks that there are threads waiting.
 - It checks whether the new_stack variable is NULL.

Pseudo-Code for Pthreads Terminated Function (1)

```
if (my_stack_size >= 2 && threads_in_cond_wait > 0 &&
     new_stack == NULL) {
  lock term_mutex;
   if (threads_in_cond_wait > 0 && new_stack == NULL) {
      Split my_stack creating new_stack;
     pthread_cond_signal(&term_cond_var);
  unlock term_mutex;
  return 0; /* Terminated = False; don't quit */
 else if (!Empty(my_stack)) { /* Stack not empty, keep working */
  return 0; /* Terminated = false; don't quit */
} else { /* My stack is empty */
  lock term_mutex;
   if (threads_in_cond_wait == thread_count-1) { /* Last thread
                                                 /* running
     threads in cond wait++;
     pthread_cond_broadcast(&term_cond_var);
     unlock term_mutex;
      return 1; /* Terminated = true; quit */
```

Pseudo-Code for Pthreads Terminated Function (2)

```
} else { /* Other threads still working, wait for work */
   threads_in_cond_wait++;
   while (pthread_cond_wait(&term_cond_var, &term_mutex) != 0);
   /* We've been awakened */
   if (threads_in_cond_wait < thread_count) { /* We got work */</pre>
      mv_stack = new_stack;
      new_stack = NULL;
      threads in cond wait --:
      unlock term mutex;
      return 0; /* Terminated = false */
   } else { /* All threads done */
      unlock term mutex;
      return 1; /* Terminated = true; quit */
} /* else wait for work */
/* else my_stack is empty */
```

Grouping the termination variables

```
typedef struct {
    my_stack_t new_stack;
    int threads_in_cond_wait;
    pthread_cond_t term_cond_var;
    pthread_mutex_t term_mutex;
} term_struct;
typedef term_struct* term_t;

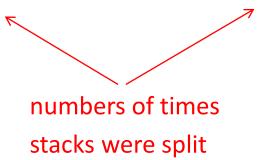

term_t term; // global variable
```

Run-times of Pthreads tree search programs

15-city problems

		First Pr	oblem		Second Problem

(in seconds)

Parallelizing the Tree Search Programs Using OpenMP

- Same basic issues implementing the static and dynamic parallel tree search programs as Pthreads.
- A few small changes can be noted.

```
pthreads
if (my_rank == whatever)

# pragma omp single
```

OpenMP emulated condition wait

```
/* Global vars */
int awakened_thread = -1;
work_remains = 1; /* true */
. . .
omp_unset_lock(&term_lock);
while (awakened_thread != my_rank && work_remains);
omp_set_lock(&term_lock);
```

Performance of OpenMP and Pthreads implementations of tree search

IMPLEMENTATION OF TREE SEARCH USING MPI AND STATIC PARTITIONING

Sending a different number of objects to each process in the communicator

Gathering a different number of objects from each process in the communicator

```
int MPI_Gatherv(
    void*
         sendbuf
                         /* in */,
        sendcount /*in */,
    int
    MPI_Datatype sendtype /* in */,
    void* recubuf /* out */,
    int* recvcounts /*in */.
        displacements /*in */,
    int*
    MPI_Datatype recvtype
                         /* in */,
    int
                          /* in */.
          root
                            /* in */)
    	ext{MPI}\_	ext{Comm}
              comm
```

Checking to see if a message is available

```
if (My_avail_tour_count(my_stack) >= 2) {
   Fulfill_request(my_stack);
   return false; /* Still more work */
} else { /* At most 1 available tour */
   Send_rejects(); /* Tell everyone who's requested */
                   /* work that I have none
   if (!Empty stack(my stack)) {
      return false; /* Still more work */
   } else { /* Empty stack */
      if (comm_sz == 1) return true;
      Out_of_work();
      work_request_sent = false;
     while (1) {
        Clear_msqs(); /* Messages unrelated to work, termination */
         if (No_work_left()) {
            return true; /* No work left. Quit */
         } else if (!work_request_sent) {
            Send_work_request(); /* Request work from someone */
            work_request_sent = true;
        } else {
            Check_for_work(&work_request_sent, &work_avail);
            if (work_avail) {
               Receive_work(my_stack);
                                                          Terminated Function for a
              return false:
                                                          Dynamically Partitioned
        /* while */
                                                          TSP solver that Uses MPL
   } /* Empty stack */
 /* At most 1 available tour */
```

Modes and Buffered Sends

- MPI provides four modes for sends.
 - Standard
 - Synchronous
 - Ready
 - Buffered

Printing the best tour

```
struct {
   int cost;
   int rank;
} loc_data, global_data;

loc_data.cost = Tour_cost(loc_best_tour);
loc_data.rank = my_rank;

MPI_Allreduce(&loc_data, &global_data, 1, MPI_2INT, MPI_MINLOC, comm);
if (global_data.rank == 0) return; /* 0 already has the best tour */
if (my_rank == 0)
   Receive best tour from process global_data.rank;
else if (my_rank == global_data.rank)
   Send best tour to process 0;
```

Terminated Function for a Dynamically Partitioned TSP solver with MPI (1)

```
if (My_avail_tour_count(my_stack) >= 2) {
  Fulfill_request(my_stack);
   return false; /* Still more work */
} else { /* At most 1 available tour */
   Send_rejects(); /* Tell everyone who's requested */
                    /* work that I have none
                                                     */
   if (!Empty_stack(my_stack)) {
      return false; /* Still more work */
   \} else \{ /* Empty stack */
      if (comm_sz == 1) return true;
     Out_of_work();
     work_request_sent = false;
      while (1)
         Clear_msgs(); /* Messages unrelated to work, termination */
         if (No_work_left()) {
            return true; /* No work left. Quit */
```

Terminated Function for a Dynamically Partitioned TSP solver with MPI (2)

Packing data into a buffer of contiguous memory

```
int MPI_Pack(
    void*
                data_to_be_packed /*in */,
                to_be_packed_count /* in */,
    int
                               /* in */,
    MPI_Datatype
               datatype
          contig_buf
    void*
                         /* out */,
                contig_buf_size /* in */,
     int
    int*
                               /* in/out */
                position_p
                                 /* in
    MPI_Comm
                comm
```

Unpacking data from a buffer of contiguous memory

```
int MPI_Unpack(
    void*
                                  /* in
                contig_buf
                                  /* in */,
     int
                contiq_buf_size
     int*
                           /* in/out */
                position_p
    void*
                unpacked_data /* out */,
                                  /* in
     int
                unpack_count
                                  /* in
                                          */,
    MPI_Datatype
                datatype
                                  /* in
    MPI_Comm
                comm
```

Table 6.10 Termination Events that Result in an Error

(in seconds)

Concluding Remarks (1)

 In developing the reduced MPI solution to the n-body problem, the "ring pass" algorithm proved to be much easier to implement and is probably more scalable.

 In a distributed memory environment in which processes send each other work, determining when to terminate is a nontrivial problem.

Concluding Remarks (2)

 When deciding which API to use, we should consider whether to use shared- or distributed-memory.

We should look at the memory requirements
 of the application and the amount of
 communication among the processes/threads.

Concluding Remarks (3)

 If the memory requirements are great or the distributed memory version can work mainly with cache, then a distributed memory program is likely to be much faster.

 On the other hand if there is considerable communication, a shared memory program will probably be faster.

Concluding Remarks (3)

 In choosing between OpenMP and Pthreads, if there's an existing serial program and it can be parallelized by the insertion of OpenMP directives, then OpenMP is probably the clear choice.

 However, if complex thread synchronization is needed then Pthreads will be easier to use.
